1. Technical data and requirements

REVELPROG-IS made by **REVELTRONICS** is a professional tool for serial memory programming. It supports wide range of **EEPROM, FLASH** and **FRAM** devices with **I2C, SPI, 1-wire** and **µWire** protocols powered with **1.0V - 5.0V** voltage levels. It has integrated **ZIF** socket (for THT devices) and **SOIC** socket (for SMD devices). It has also connector for **in-circuit serial programming (ICSP)** with buffered I/O. Due to **USB 2.0** interface memory operations are really fast.

Technical data:

- power supply and communication via USB 2.0 (hardware level, bulk transfer),
- supported protocols: I2C, SPI, 1-WIRE, MICROWIRE,
- supported devices with 1.0V - 5.0V power supply,
- programming device powered from programmer (1.0 - 5.0V, I_{max} = 100mA) or from external circuit (1.0 - 5.5V),
- operation speed (read/write) up to 10Mbit/s,
- ZIF-32 + SOIC-8 (150mil) integrated sockets,
- connector for in-circuit serial programming (ICSP) with buffered I/O,
- auto adaptive I/O pins connected only for programming time (Hi-Z in IDLE state),
- short circuit and overload protection,
- device manufactured in EU, made in Poland.

Requirements:

- USB 2.0 or above,
- Windows 11, 10, 8, 7, Vista or XP (32 and 64 bit) + .NET Framework 4¹ installed in OS.

¹ .NET 4.0 Client Profile or above (can be downloaded from MICROSOFT: <http://www.microsoft.com/en-us/download/details.aspx?id=17718>)

2. Features and applications

REVELPROG-IS is used in many applications such as: **car electronics & automotive** (reprogramming modules, radio-code, mileage correction, immobilizers, gps navigations), **computer service** (data recovery, reflashing/upgrading/programming BIOS chips on motherboards of PC, notebooks, copier & fax machines, printers, SFP/QSFP/XFP transceivers etc.), **RTV/AGD service** (TV & TV tuners, digital cameras, multifunction devices etc.) and many other devices equipped with serial I2C/SPI/MICROWIRE EEPROM and FLASH chips. Due to the possibility of change voltage level (in range of **1.0 - 5.0V**) programmer supports both older and newer devices (e.g. latest devices equipped with 1.2V and 1.8V low-voltage chips). Device is equipped with **ICSP connector** that allows in-circuit serial programming without unsoldering the chip from board - **built in additional protection** (buffered I/O, short circuit and overload protection) increase reliability and safety of such operations.

Main features:

- reading / writing / erasing functions with user-friendly application interface,
- supported binary files (*.bin, *.rom, *.epp etc.) and Intel-Hex (*.hex) with possibility to load file to the buffer, edit it, calculate checksums, swap-bytes, save modified bytes as patterns, compare with chip etc.,
- programming in socket or in external circuit (without unsoldering the chip),
- the target application device can be either powered by REVELPROG (possibility to change VPP and logic levels: 1.0V / 1.5V / 1.8V / 2.5V / 2.8V / 3.3V / 5.0V) or powered by an application with external power supply (1.0 – 5.5V),
- build in additional protection: buffered I/O pins internal connected only during programming + short circuit and overload protection (reduces the risk of damaging parts due to connection mistake),
- integrated sockets (ZIF + SOIC) with auto adaptive I/O pins reduces requirement of additional adapters,
- short programming time², e.g. WINBOND W25Q80BV (8Mb): read 0.9s (8,4Mb/s), write 3.3s (2,4Mb/s), MICRON N25Q128A (128Mb): read 12.8s (10Mb/s), write 37.6s (3,4Mb/s),
- useful tools such as: save/load patterns with changes, i2c/spi custom scripts, auto backups, file comparing etc.

² Due to USB 2.0 hardware layer (BULK mode) maximum real transfer is up to 10Mbit/s for read/write operations but in many cases transfer is limited by read/write time cycle from/to memory (e.g. write is always slower than read). Write time does not include chip erase time (you can find tCE in device datasheet) and verification (read) time. There is possibility to change write sequence (e.g. without erasing and verifying) but most devices require at least chip erase before write operation.

3. Installation of software and USB drivers

Requirements:

PC application is compatible with MS Windows³ 11, 10, 8, 7, Vista and XP (32 and 64-bit versions). You will need also .NET Framework 4.0 to run application (probably already installed⁴ in your OS)

Software installation:

Software installation is typical for Windows. Just run setup (*REVELPROG-IS_v1-x_Setup*) and follow instructions (next, next, finish;). You may be prompted for USB driver installation (accept it). Shortcut to REVELPROG-IS app will be added to the desktop. Application is ready to run.

Drivers installation:

In most cases drivers will be successful installed during application installation. Drivers may be installed also later from application (menu "help" -> "install drivers").

Windows XP users will have to install drivers after first device plugged-in - just select drivers location in installation folder (by default it is "*C:\Program Files\REVELTRONICS\REVELPROG-IS\drivers\REVELPROG-IS*"). If you miss it, you can install drivers later manually (run device manager, find "REVLPROG-IS" device on the list, right click and update driver, select driver location).

Windows 8/10/11 x64 users will have to install drivers from REVELPROG-IS application by using "Zadig" installer (menu "help" -> "install drivers with Zadig"). You should select REVELPROG-IS device on the list and install WinUSB driver, video: <https://www.youtube.com/watch?v=6AFD3yBsRNc>

³ Windows XP with SP3 installed (service pack 3). Windows 7 with SP1 installed.

In case of "fresh" install of OS you may need also "Microsoft Visual C++ 2010 Redistributable Package" (<http://www.microsoft.com/en-us/download/details.aspx?id=5555>)

⁴ if NOT, you can download and install it directly from Microsoft web page: <http://www.microsoft.com/en-us/download/details.aspx?id=17718>

4. First steps with REVELPROG-IS application

4.1. User interface

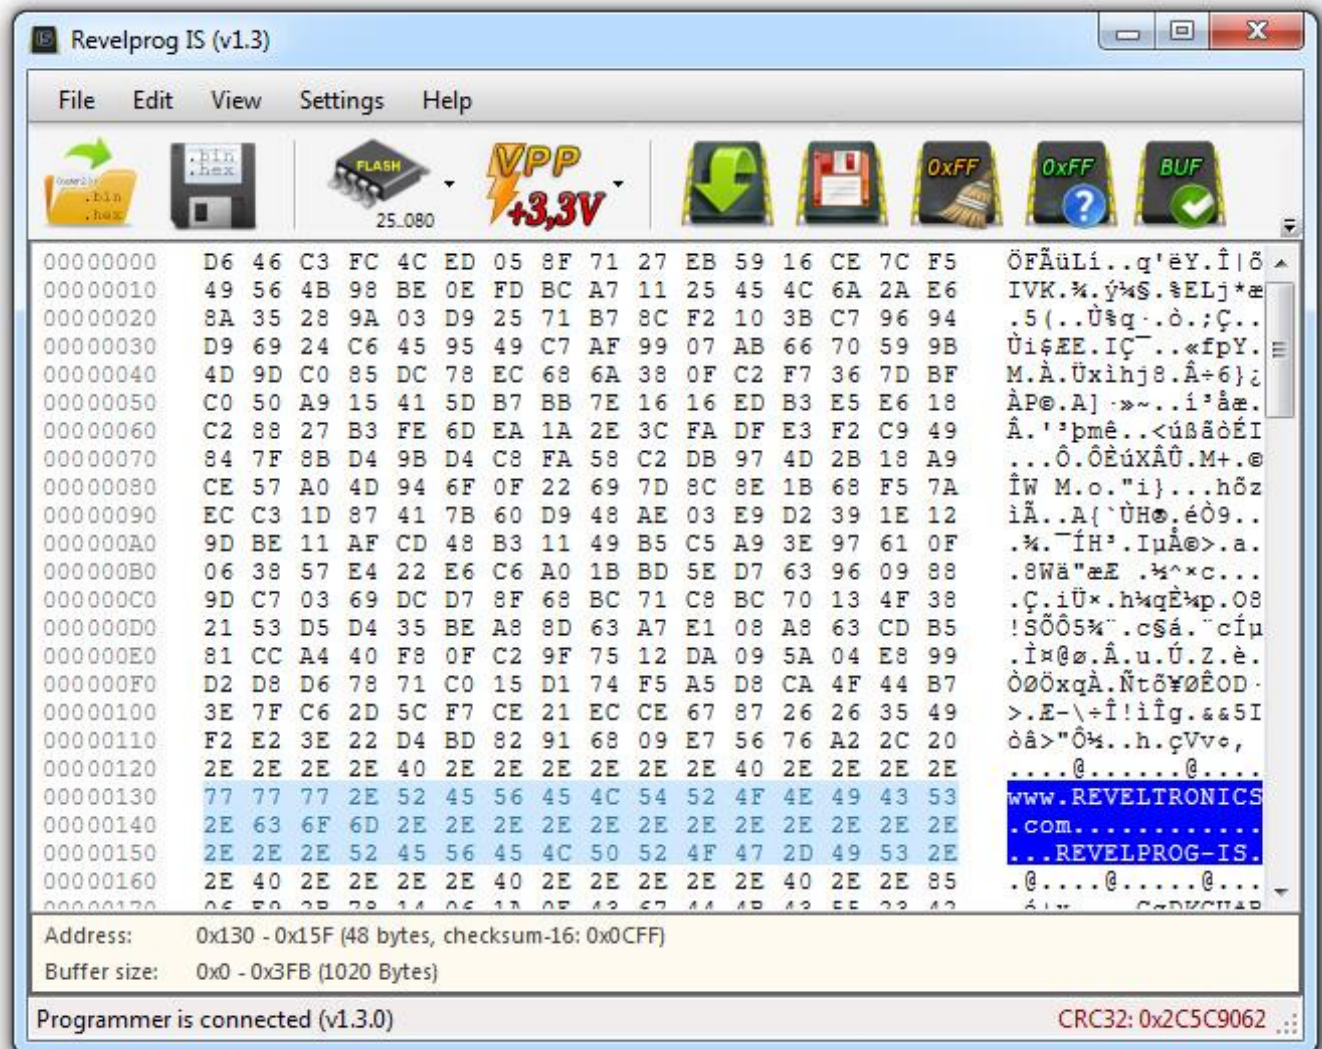

Application interface is user-friendly. All main functions can be run directly from shortcut icons (all icons are activated after device connected). Please move cursor above specific icon to see additional tooltip.

Memory buffer is displayed in hexadecimal + ASCII format. There is possibility to edit buffer as bytes and as ASCII characters.

Additional information is displayed in lower area:

- buffer information: buffer size in bytes, buffer addresses range and current address (or addresses range) of cursor position (selection) with calculated checksum-16 (from selected bytes),
- status bar (programmer version info or last operation info),
- CRC-32 checksum calculated from buffer or opened file (click on "CRC32" to recalculate checksum)

4.2. Device programming

Device type should be selected from the device database before any operation ("chip select" icon). Voltage will be set automatically. It can be changed manually by clicking VPP icon. In case of ICSP programming with external power supply, VPP should be set to the same level as memory power supply.

4.2.1. Reading

Before device reading operation, memory type should be chosen. Please check also VPP voltage (you may need to change it in case of low-voltage chips). Click READ icon (memory chip with green arrow).

Programmer will read device. Memory content will be loaded into the buffer. Buffer can be saved to external file. You can also edit the buffer and reprogram the device.

Please note at the CRC32 checksum (right corner at the bottom). If checksum is equal after each read than the risk of read with error usually does not exist. It is a good practice to make memory backup to external file before any writing.

The reading may be incorrect due to communication error or broken chip.

4.2.2. Writing

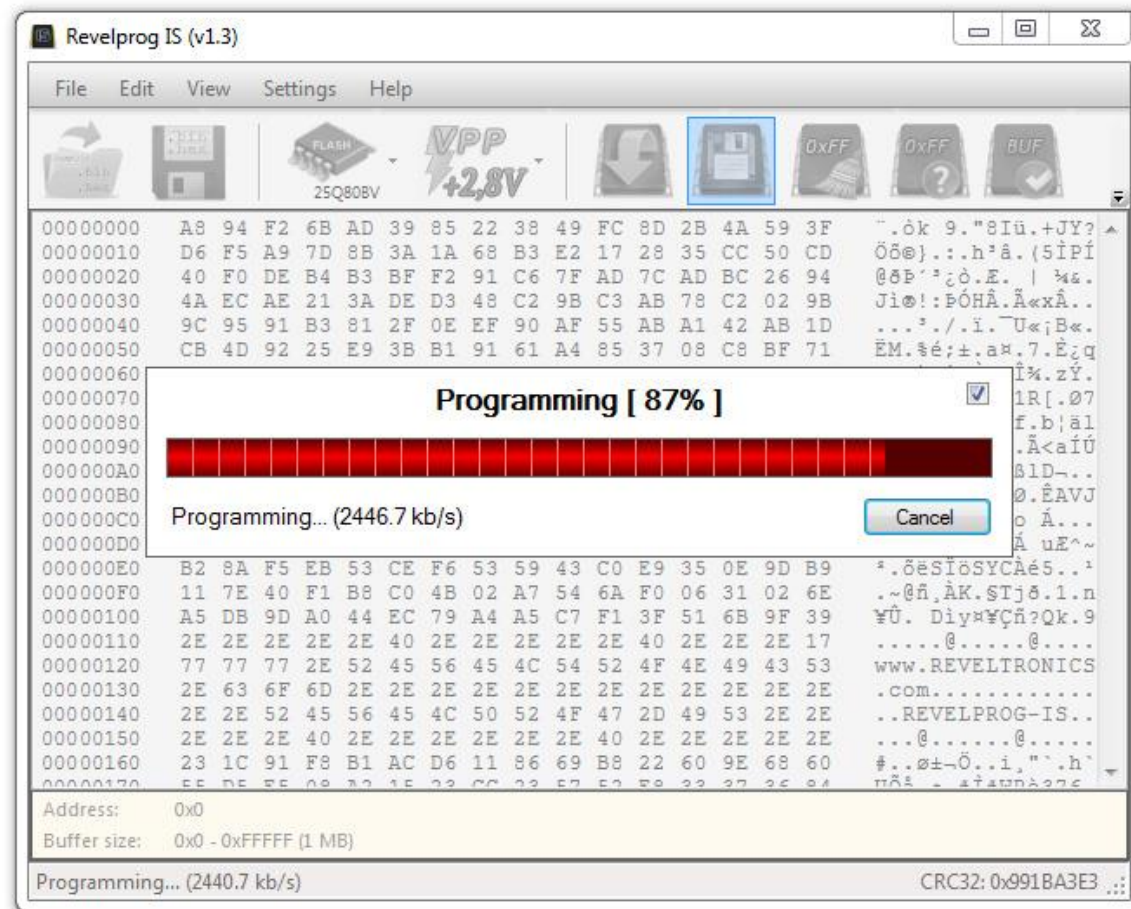

Before device programming operation, (1) memory type should be chosen and (2) buffer should be filled with data. You can load data from external binary (*.bin, *.rom, *.epp etc.) or Intel-Hex (*.hex) file. Please check also VPP voltage – it may be changed in case of low-voltage chips. Please click “WRITE” icon (memory chip with red-orange floppy disk).

Programmer will erase the device, write data to memory from the buffer and make verification process. There is possibility to change writing sequence from menu: *Settings* -> *Write sequence*. Verification process will read the device after writing and compare reading with the buffer. If verification pass than memory is successful programmer. Verification error may occur due to communication error, secured or broken chip.

4.2.3. Erasing

To erase memory, empty buffer can be loaded and programmed into a memory. In most cases this operation is not necessary, because programmer supports fast erase procedures (Page Erase, Block Erase and Chip Erase). Please click “ERASE” icon (memory chip with 0xFF and broom) for erasing operation.

Please note that erasing progress is not displayed at progress bar. For high density FLASH memories erase process may took quite long (even few minutes!).

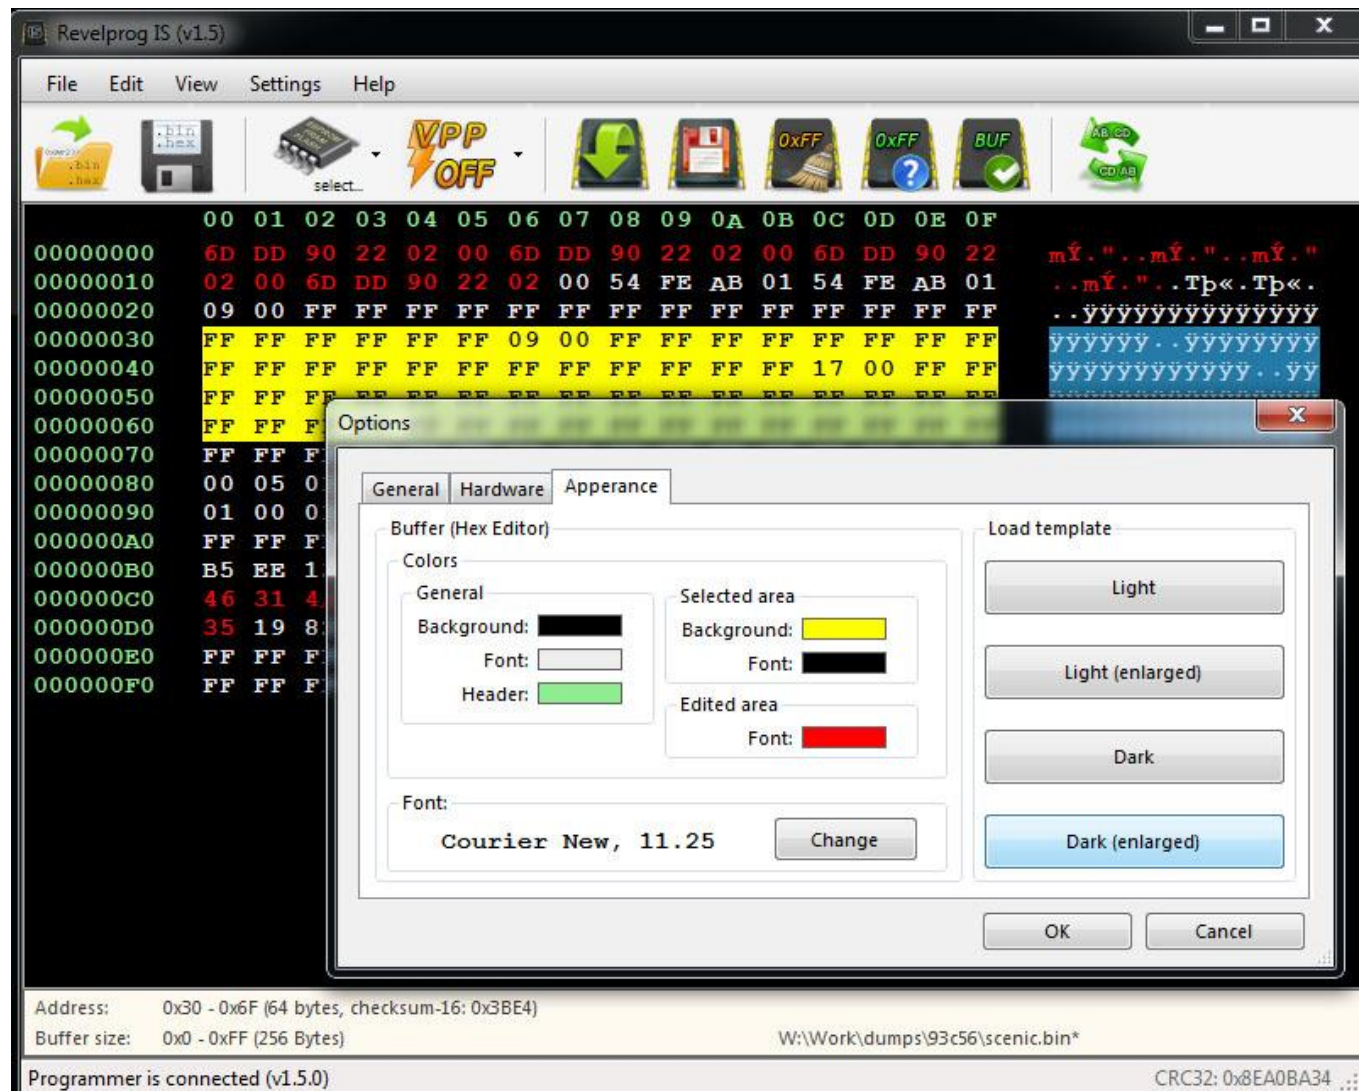

4.3. HEX editor features (buffer editing)

4.3.1. HEX editor

Buffer can be edited from application level. In the first column there is current address displayed. In the second column there is memory contents displayed (as bytes in hexadecimal mode). In the third column there is ASCII representation of memory contents. All buffer operations are allowed (e.g. CTRL+C, CTRL+V etc.). Modified buffer can be saved to external .bin or .hex file.

4.3.2. Appearance

There is possibility to personalize hex editor, e.g. color and font changes. Bigger font and dark contrast colors will enhance your work with editor especially on high resolution displays.

4.3.3. Fill buffer...

Fill selected bytes with constant bytes or defined pattern.

1. Open context menu (right click) and choose fill...

2. Enter pattern...

3. Take profit - you have just saved some time...

4.3.4. Patterns - export changes to file

All manual changes (highlighted bytes) can be exported to external file (pattern). Later, at any moment there is possibility to load pattern file and all changes will be imported, without modifying other bytes in the buffer. Simple, fast and powerful.

4.3.5. Swap bytes

Swap bytes operation will change byte order in 2-bytes word. For example, swapped word 0xABCD will be equal to 0xDCBA. This functionality is very useful for memories with two addressing modes, e.g. for microwire 93... series 16-bit chips. REVELPROG supports both addressing modes (8-bit and 16-bit) for these devices.

4.3.6. Clear buffer or generate random buffer

There is possibility to clear buffer (0xFF) or generate random buffer from *Edit* menu. Buffer length will be equal to memory size. *CTRL + N* shortcut will clear buffer and *CTRL + R* shortcut will generate random buffer.

4.3.7. CRC32 and Checksum-16

Click "CRC32" in right-bottom corner to calculate CRC32 checksum from the buffer. Changing single byte in the buffer will change CRC32 checksum so this feature is useful in comparison of sequential reads or files. Checksum-16 is calculated in real time from selected bytes in the buffer area and it's displayed in buffer info. This is most common algorithm for checksum used in wide range of devices (checksum of mileage, operation hours, serial numbers etc.) To calculate Checksum-16 from all addresses select all bytes in the buffer area (*CTRL+A*).

4.3.8. File format conversion: .bin <-> .hex

I Application can be used also as a simple file converter (binary to intel-hex and vice versa). To convert file from one type to another, just open file (load to buffer) and save it in another format.

4.3.9. DiffChecker (file comparing)

DiffChecker tool allows to compare 2 bin or hex files. All differences will be selected and grouped. Press F3/F2 to find next/previous difference region. You can save all differences to external file as a pattern (feature described in Chapter 4.3.4). If files are totally different then first 1000 different regions are marked.

The screenshot shows the DiffChecker application window. The title bar reads "DiffChecker". The main area is divided into two sections, each showing a comparison of a binary file:

- Top Section:** File "W:\Work\dumps\93c56\scenic1.bin" (256B (0xA48E)). It displays a hex dump from address 00000000 to 000000F0. The ASCII column shows characters like "mÝ." and "Tp«.Tp«.". Differences are highlighted in blue.
- Bottom Section:** File "W:\Work\dumps\93c56\scenic2.bin" (256B (0xA70B)). It displays a hex dump from address 00000000 to 000000F0. The ASCII column shows characters like "}zÝ.3.}zÝ.3.}zÝ." and "3.}zÝ.3.Tp«.Tp«.". Differences are highlighted in blue.

A red status bar at the bottom of the window contains the text: "Files are different (3 different regions). Current address: 0xFF".

4.4. Additional features

4.4.1. Blank test

Blank test checks if chip is empty. Test will be canceled as soon as first programmed cells will be detected (there is no need to read full memory).

4.4.2. Compare with the buffer

Operation compares buffer with the contents of memory. Operation will be cancelled as soon as first difference will be detected.

4.4.3. VPP selection

VPP is set for both: programming voltage and signal levels. VPP can be changed with 0.1V step in range of 1.0 - 5.0 volts. This feature is very useful in few cases:

- in order to program low-voltage variant of the device (e.g. 1.8V instead of 3.3V),
- in case of in-circuit programming with external power supply -> programmer voltage should be the same as external circuit voltage or VPP should be disabled (VPP OFF),
- in case of in-circuit programming without external power supply. In many cases there is no need to set nominal voltage for external board. For example: memory operates in range of 2.6 to 3.6 volts. Nominal voltage for external board is 3.3V. Setting the lowest operational voltage (2.6V) will be enough to power and communicate with the memory and at the same time will be too low to power all circuits around. First of all, if there is main microprocessor on the board than it will not communicate with the external memory (because it will be in "reset" state due to low voltage to operate) so it will be possible to communicate with this memory using external programmer. Secondly, you will save current consumption because devices in reset state consume much less power. This trick is not always possible, so if you can't communicate with the device in external circuit try to plug-in external power supply or unsolder the chip and program it in socket. Please read Chapter 5 for more details.

4.4.4. Device identification (Chip ID) for FLASH SPI, DATAFLASH and 1-wire devices

In order to read Chip ID please select "Tools" -> "Read ID" (F10). Operator should know operating voltage for the device because REVELPROG-IS supports also low voltage chips and reading chip ID without knowledge about chip power supply level is risky (setting 3,3V for 1,8V chip will damage it even during chip id reading). For FLASH devices programmer will read 4 identification bytes of data (JEDEC ID)– 1st byte is Manufacturer ID, 2nd and 3rd bytes are Device ID and 4th byte is Extended ID. For some FLASH SPI devices programmer can auto select recognized chip from memory database. You can read about identification bytes in device datasheet. For 1-wire devices programmer will read 64-bit unique identification number.

4.4.5. Quad SPI (QSPI) configuration for FLASH SPI

Some of FLASH SPI devices may require to enable QSPI mode before soldering it in external device. This will require to change one of configuration or status registers in device memory map.

TIP: in most cases, specially when you reprogram FLASH SPI there is not necessary to change any configuration bits.

To enable or disable Quad mode you can use dedicated tool (Tools -> Quad SPI) – it will work with most popular FLASH SPI devices (e.g. Winbond and Spansion). For other devices it may be necessary to write custom script (with Custom Script tool – described in Chapter 6) to enable or disable QSPI mode manually by changing QSPI bits in required registers. You can read how to change Quad SPI mode for your device in device datasheet.

4.4.6. SFP/QSFP/XFP Transceivers support

REVELPROG-IS has dedicated tools for optical transceiver support. There is SFP/QSFP/XFP adapter required with external power supply. MSA Standard is supported (e.g. SFF-8472, SFF-8636, INF-8077i). Dedicated functions allows to enter manufacturer/host password and program write protected transceivers, brute force password (searching password for protected transceivers with unknown password), change manufacturer info, model, serial number etc. and recalculate checksums directly from REVELPROG-IS application. Please check Chapter 7 for more details.

4.4.7. Auto backup

Every read operation there is backup file (.bin) generated (by default it is user documents folder in system). By default maximum 16 files are created (oldest are deleted) and size is limited to 8Mbit devices. You can change these parameters in Settings -> Option -> File -> Autobackup (you can set unlimited number of files and size).

4.4.8. Custom Scripts for SPI, I2C, 1-Wire

Custom Script Tool allows to execute user defined commands on SPI, I2C or 1-Wire bus, e.g. unlocking device, read/write custom registers, change sector protection bits, write OTP registers and much more. Please check [Chapter 6: Custom Script Programming \(I2C / SPI / 1-wire bus\)](#) for more details or forum tutorial <https://forum.reveltronics.com/viewtopic.php?f=22&t=280> with examples.

4.4.9. W74Mxx Secure Authentication Flash

Authentication Flash W74M series is standard W25Q series Flash with additional layer for authentication. With W74xx Authentication Flash Keys Tool for REVELPROG-IS it is possible to programm new keys, verify if used key is correct (authentication pass) or increment monolithic counter. It is NOT possible to read stored keys. More information about W74M series and programming keys:

<https://forum.reveltronics.com/viewtopic.php?f=32&t=972>

4.4.10. Automatic mode with production file and command line (Beta)

REVELPROG-IS application is GUI based application so Automatic Mode tool is also GUI based. It will not work from command line interface, but it can be started from command line interface with additional parameters. It is possible to run REVELPROG-IS application from command line with *-productionFile "path.txt"* parameter, so it will run and load production file on start-up. In production file it is possible to configure: device name, operating voltage, operation type (READ, WRITE or ERASE), file path (for write or read operation), pre-script and post-script paths (for custom script tool). Please read below tutorial with video example how to use automatic mode tool:

<https://forum.reveltronics.com/viewtopic.php?f=32&t=913&p=3822>

5. In-Circuit Serial Programming (ICSP)

Caution! Before ICSP programming please read following instructions!

ICSP programming is recommended only for advanced users. There is required technical knowledge and being familiar with specific chip. You should read carefully device datasheet, especially memory pinout, addressing modes and voltage levels.

Programmer is equipped with 10-pin ICSP socket (IDC10). There's only 8 pins used (pin-9 and pin-10 are not internally connected). Pinout numeration (1-8) is the same as memory pinout in datasheet for DIL8/SO8 package.

There will be various signals at these pins during chip programming (digital and analog signals). These signals are assigned automatically after memory chosen (in application) and are set only during memory operation.

5.1. Addressing in external circuit

All hardware addressing outputs for EEPROM 24.. series (pin 1,2,3 ie A0, A1, A2) must have low voltage level (GND). If chip in circuit is addressed in other way (e.g. there are few the same chips, which require various addressing) then communication will fail. In this case you can (1) set correct addressing in application ("External addressing" option during memory selection) or (2) set default "0" addressing with the programmer (connect addressing wires to the chip and in the same time disconnect them in external circuit). The safest option is to unsolder the chip and put it to integrated programmer socket.

Addressing 8/16-bit for EEPROM 93 series also needs special care. In circuit addressing wire (pin 6) can be connected to low or high state (it's defining addressing mode if memory support both modes). Depends on your chip selection in application (8/16 bit) programmer gives LOW or HIGH state on this pin. If you choose wrong addressing (e.g. in circuit it is low state and programmer outputs high state) than you will make short circuit. In most cases it's not necessary to connect addressing wire (pin 6) for microwire 93 series - it's enough to select right mode from application (16-bit in most cases).

If you are not 100% sure about connections, DO NOT program in circuit – unsolder the chip and program it with integrated socket.

5.2. Write protection in circuit (WP/PRE pin)

A lot of serial devices have WP (Write Protect) or PRE (Protection Enable) input. Low state on this pin (ground) protect the device from erasing and writing. Programmer outputs a high state during erase or write operation. If in external circuit write protect pin is connected to ground (common case), and programmer will output high state on this pin, than it will lead to short circuit. There are 3 common solutions in this case: (1) do not connect write protect pin (erase/write will not work), (2) disconnect write protect pin in circuit (connect it only to programmer) or (3) unsolder the chip and program it in programmer's socket.

WP (Write-Protect) or PRE (Protection Enable) pin can be found e.g. in FLASH SPI 25.. (pin 3), FLASH SPI 26... (pin 3), FLASH SPI 45... (pin 5), EEPROM I2C 24... (pin 7), EEPROM SPI 25.. (pin 3), EEPROM SPI 35... (pin 3), EEPROM SPI 95... (pin 3), EEPROM MICROWIRE 93... (pin 7).

5.3. Power supply in external circuit

The target application device can be either powered by programmer [voltage level (VPP) can be chosen from: 1.0V – 5.0V - please read Chapter 4.4.3] or powered by an application within a voltage range of 1.0V to 5.5V. If chip is already powered in external circuit, than VPP should be set to the same voltage as external power supply (0,1V accuracy is tolerated). Absolute maximum rating at programmer's I/O pins is 5.5V - exceed this value may damage protection buffers in programmer.

5.4. Limits and possible issues during in-circuit programming

In some cases there is no possibility to program chip in application. This can be due by many reasons, such as:

- to long signal wires,
- too much load capacity in circuit,
- incorrect pull-ups or pull-downs on signal wires,
- incorrect addressing,
- bus conflict (memory is during communication with other device),
- impedance not match,
- additional capacitors, diodes bus-switches etc. in circuit.

In case of power supply from programmer, current is limited to 100mA for safety reason. If application requires more power, than external power supply should be connected.

In case of incorrect connections, short circuit or overload, following error (pict.) will be displayed and all I/O will be disconnected. Delay of protection trigger is 5-35ms so you still have to be careful. Programmer implements "VPP-boost" mode which allows for 3x higher current consumption at the first 30ms of operation (e.g. for capacitor charging). There is also possibility to increase in settings overload protection to 200mA.

If you are not sure about connections or voltage levels DO NOT program in-circuit. It is much safer to unsolder the chip and program it in the socket.

5.5. SOIC Clip

Devices in SOIC package can be connected with SOIC CLIP (e.g. POMONA 5250 for SOIC-8 and POMONA 5252 for SOIC-16). Programming with a clip is recommended only for advanced users (many traps for young players). Clip is a precision measuring device - **before connecting the clip please read chapters 5.1 – 5.4**. Please follow tips below to avoid any accidental damage to the clip:

- clip should be used only with SMD chips with SO-8 package (150mil or 200mil),
- clip should NOT be used with physically damaged chips (not straight pins or excess of tin),
- do NOT touch contact pins – any attempt of mechanical interference will damage contact pins,
- it is NOT recommended to use the clip when device was previously soldered in not professional way (pins may not contact to memory pads; there is also risk of damage to the contact elements). In such case it is recommend to use external adapter SOIC-8 150mil or SOIC-8 200mil,
- it is NOT recommended to use the clip on a desoldered device ("in air") – read and write may be incorrect (specially for fast devices, e.g. FLASH SPI). All devices should be programmed in external circuit or in adapter, because only this method guarantees proper operations (in external circuit there are additional filtering elements while external adapter guarantees the shortest connections). If you really need to connect desoldered device in the clip, please do it very carefully. For FLASH SPI you should use as short wires as possible (5cm) and decrease SCK frequency to 10% (Settings -> Options -> Hardware -> SCK = 10%). It not guarantees success but increases your chances.

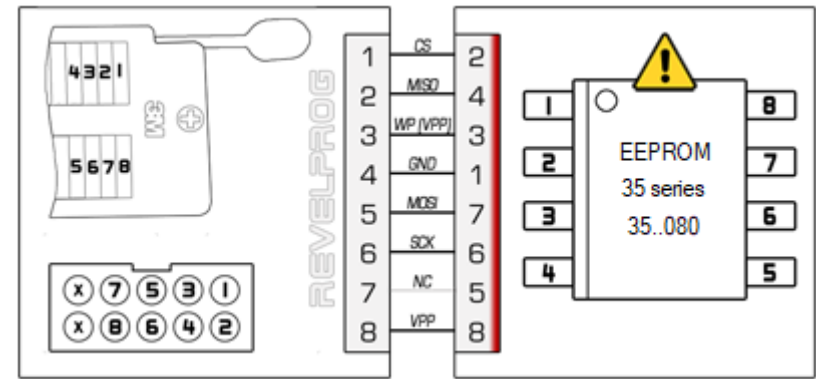

Connecting the CLIP

Connection schema is displayed in application during device selection. In most cases connection is straight „1 to 1“ as you can see on the left picture (programmer pin 1 should be connected to memory pin 1, programmer pin 2 to memory pin 2, pin 3 to pin 3 etc.). In some cases connection is not straight, e.g. for 35080 memory (programmer pin 1 to memory pin 2, programmer pin 2 to memory pin 4 etc. - picture on the right).

Straight connection „1 to 1“ for FLASH SPI

Not straight connection for 35080

First of all you should identify PIN 1 in the device⁵. Secondly you should connect wires to the clip and then clamp the clip on the device (so connections will fit to schema). It is recommended to use dedicated ISP 10-pin socket in programmer. Please do not suggest with color of wires in tape – only pin numbers are important. Example movie with POMONA CLIP connecting for 1-wire device: <https://youtu.be/r2T78o7oxfQ?t=145>

⁵ Pin no. 1 in the device is pointed with small dot in corner or with milled edge (as you can see at picture in schema above)

5.6. Troubleshooting for in-circuit programming

If you can program device in programmer's socket (or adapter) with success, but you cannot program it in circuit than there are few things that you can check. First of all, make sure that:

- all wires are connected properly (please take special care for pin contact in case of programming with SOIC CLIP),
- external circuit is powered properly and there is no voltage conflict on power bus,
- SPI lines: CS, (MOSI), (MISO) and (SCK) have pull-up resistors to power supply (4.7k - 10k),
- communication lines do not have additional elements, such as diodes, bus-switches, transistors etc.
- there is no communication conflict on the bus (e.g. processor and all other devices connected to shared SPI bus should be in RESET state).

Secondly, if problem still exist, there are still may be some tricky issues. Few examples with solutions below:

- noise and overshooting (communication errors, random read) – possible solutions:
 - decrease SPI clock to 10% for FLASH SPI devices (menu *Settings* -> *Options* -> *Hardware* -> *FLASH SPI SCK*),
 - impedance matching and termination for external circuit (and wires) by using e.g. termination resistors on signal wires. There is no universal value of resistance (each circuit is different) but in most cases 100 - 1000 Ohm resistors in serial for CS, (MOSI) and (SCK) will be enough:

- CS line decoupling (33pF - 220pF to ground as close as possible to the device in-circuit),
- VCC line decoupling (100nF to ground as close as possible to the device in-circuit),

- to low voltage level during erasing and/or writing (erase error / communication error):
 - when external device (in external circuit) is powered from programmer, than there are also other devices powered too (on the same power line) and due to higher current consumption output voltage may be too low for erase and write operations. In this case it is recommended to set VPP slightly higher (e.g. +0.3V) or use external power source and set the same VPP level in application.
- bus conflict (random read or communication error during read):
 - in some cases after device power up, the main processor is starting communication with slave devices (e.g. with memory you are trying to read) – in this case it will be conflict on the bus (random read or communication error). All devices connected to the same communication bus should be forced to be in RESET state. Sometimes it is enough to use external power supply and wait about 2-3 minutes for initial procedure finished and then try to communicate with the memory (when all devices are in idle state and bus is free). The other tricky way is to use minimum voltage level to communicate with memory and this voltage level may be too low for other devices so they will stay in RESET state and will not interrupt communication. On the other hand, to low voltage level may be not enough to success for erase and write operations.

In some cases design of external circuit does not physically allow for in-circuit programming. In this case chip should be unsoldered and programmed in programmer's socket or adapter.

6. Custom Script Programming (I2C / SPI / 1-wire bus)

Custom script programming for I2C/SPI/1-wire bus in case of REVELPROG is a some kind of "bus pirate" tool for serial communication. With REVELPROG-IS Customs Script tool **there is possibility to execute any commands in any sequence with precise delays on SPI, I2C or 1-wire bus**. You can write script to execute commands for unlocking device, read and write hidden (or not) registers, change sector protection bits, write OTP registers and much more.

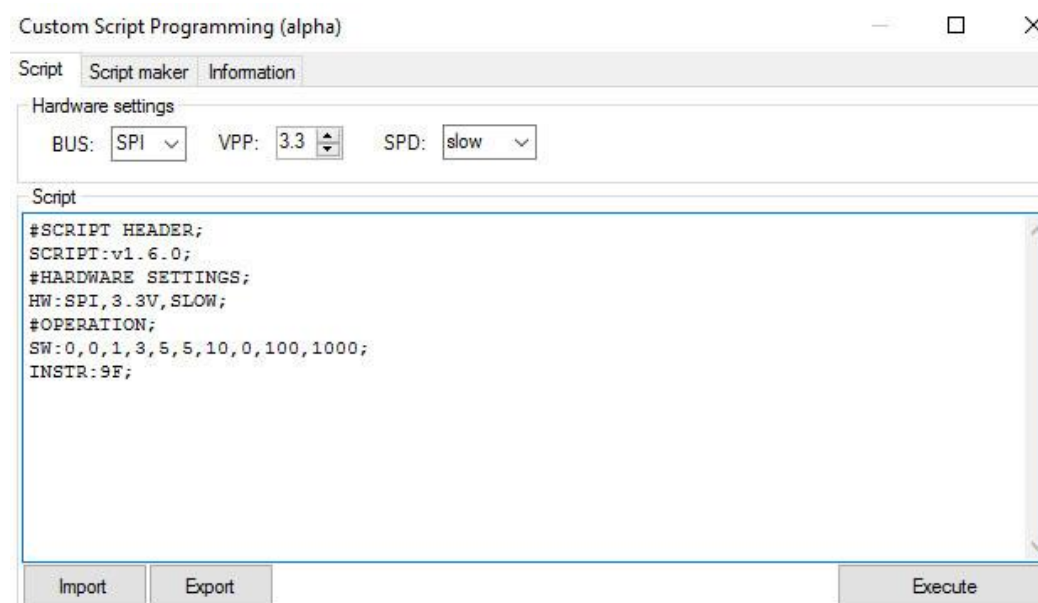

In practice it is also very useful tool for electronic enginners and embedded programmers, because **there is possibility to communicate with any serial (I2C, SPI and 1-wire) device**. External device or module can be also powered from REVELPROG-IS (1.0 - 5.0V with 0.1V threshold). Only few connection lines are required for communication (4 wires for SPI or 2 wires for I2C + optional 2 wires for external device power supply).

6.1. Script construction

Typical script consists of (1) #SCRIPT HEADER - information about software version, (2) #HARDWARE SETTINGS - voltage selection (VPP), bus selection (I2C/SPI) and communication speed, (3) #OPERATION (1 to n). Each script has to have at least one operation defined.

Each #OPERATION consists of (1) 'SW' operation parameters: number of bytes to read/write, delay settings, (2) 'INSTR' instruction - sequence of bytes for single instruction, (3) 'DATA' data to write (optional) - sequence of optional bytes for write after single instruction

Example construction of typical script with header (software version v.1.6.0), hardware settings (SPI bus, 3.3V voltage, slowest speed) and single operation with 1-byte 9Fh command is presented on right image:

6.2. Script syntax

- "#" defines sections, e.g. #SCRIPT HEADER; (header), #HARDWARE SETTINGS; (hardware settings), #OPERATION; (for each operation),
- ";" is placed at the end of each command,
- ":" is placed directly after command words, e.g. SCRIPT: (script version), HW: (hardware settings), SW: (software settings - operation parameters), INSTR: (instruction), DATA: (write data);
- "," separates parameters for each command (e.g. between "INSTR:" and ";" comma separates instruction bytes)
- "//" precedes comments which are ignored by script executor

Each script should have single #SCRIPT HEADER, single #HARDWARE SETTINGS and at least one #OPERATION (or more).

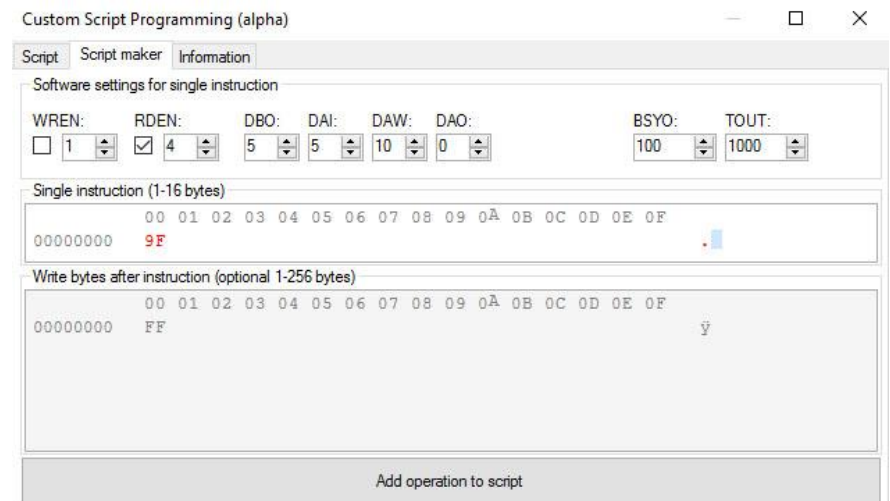

6.3. Script maker with GUI

Script maker will help you prepare multiple operations with correct syntax. You need to set few parameters for each operation:

- WREN (Write Enable) + number of bytes to write in single operation,
- RDEN (Read Enable) + number of bytes to read in single operation,
- DBO (Delay Before Operation) - optional delay in ms before operation,
- DAI (Delay After Instruction) - optional delay in ms after instruction,
- DAW (Delay After Write) - optional delay in ms after write,
- DAO (Delay After Operation) - optional delay in ms after operation,
- BSYO (Busy Operation) - maximum time in ms for write end (e.g. maximum wait time for busy flag in FLASH SPI or for ACK in I2C devices)
- TOUT (Timeout) - maximum PC timeout in ms for operation end (it is recommended to set timeout greater than sum of all other delays).

Please note that:

- Read/Write length are 0 based (0 means 1 byte, 255 means 256 bytes) and with WREN=0/RDEN=0 length parameter is ignored,
- "SW:" and "HW:" byte format is decimal,

- "INSTR:" and "DATA:" byte format is hexadecimal.

Operation code generated by script maker from above example::

```
#OPERATION;  
SW:0,0,1,3,5,5,10,0,100,1000;  
INSTR:9F;
```

As you can see SW parameters are equal to script maker parameters:

```
SW:WREN[0-1],WriteLength[0-255],RDEN[0-1],ReadLength[0-255],DBO[0-250],DAI[0-250],DAW[0-250],DAO[0-250],BSYO[0-n],TOUT[0-n];
```

6.4. Script execution sequence

Each script is executed with following sequence:

1. SET HW (BUS, VPP, SPEED)
2. EXECUTE OPERATION 1 (SET SW -> DBO -> INSTR -> DAI -> WRITE -> DAW -> BSYO -> READ -> DAO)
3. EXECUTE OPERATION 2
4. ...
5. EXECUTE OPERATION N
6. RESET HARDWARE*

*instead of RESET HARDWARE you can end script with additional command #LEAVEVPPENABLED so power supply will be not disabled after script execution

6.5. Additional script syntax

#LeaveVppEnabled

Use this command at the end of each script to left VPP enabled after script execution.

#INSTR and #DATA formatting

It's allowed to ignore commas and spaces for input data for above fields (e.g. #DATA:0011223344; instead of #DATA: 00, 11, 22, 33, 44;)

#DATA:BUFFER

It will import data bytes directly from application buffer, so you do not have type data bytes in script directly. Address will be incremented in background, so it will import bytes from buffer with proper offset. You can also define custom offset, e.g. #DATA: BUFFER,8;

6.6. Pre-script and Post-script

Custom script can be also used as a pre-script or post-script during normal memory operation. Enter CTRL + ALT + SHIFT +S to show script tabs in memory database. You can also use pre- and post- scripts with [Automatic Mode Tool](#).

6.7. Script examples

Please take a look at forum tutorial for more information and script examples:

<https://forum.reveltronics.com/viewtopic.php?f=22&t=280>

7. SFP / QSFP / XFP transceivers

REVELPROG-IS allows programming SFP, QSFP and XFP transceivers. Hardware adapter with SFP/QSFP/XFP connectors and external power supply is required. MSA Standard is supported (e.g. SFF-8472, SFF-8636, INF-8077i). Special features allows to enter manufacturer / host password and program write protected transceivers, brute force password (searching password for protected transceivers with unknown password), change manufacturer info, model, serial number etc. and recalculate checksums directly from REVELPROG-IS application.

7.1. Adapter connection

Please connect external QSFP SFP XFP Adapter for REVELPROG-IS using 10-pin connector. Please connect power supply to adapter. Please insert transceiver to dedicated transceiver slot. Only one transceiver should be inserted at the same time.

Example of connected QSFP SFP XFP Adapter (please note that power supply of adapter is also from PC USB port):

7.2. Device selection and memory map

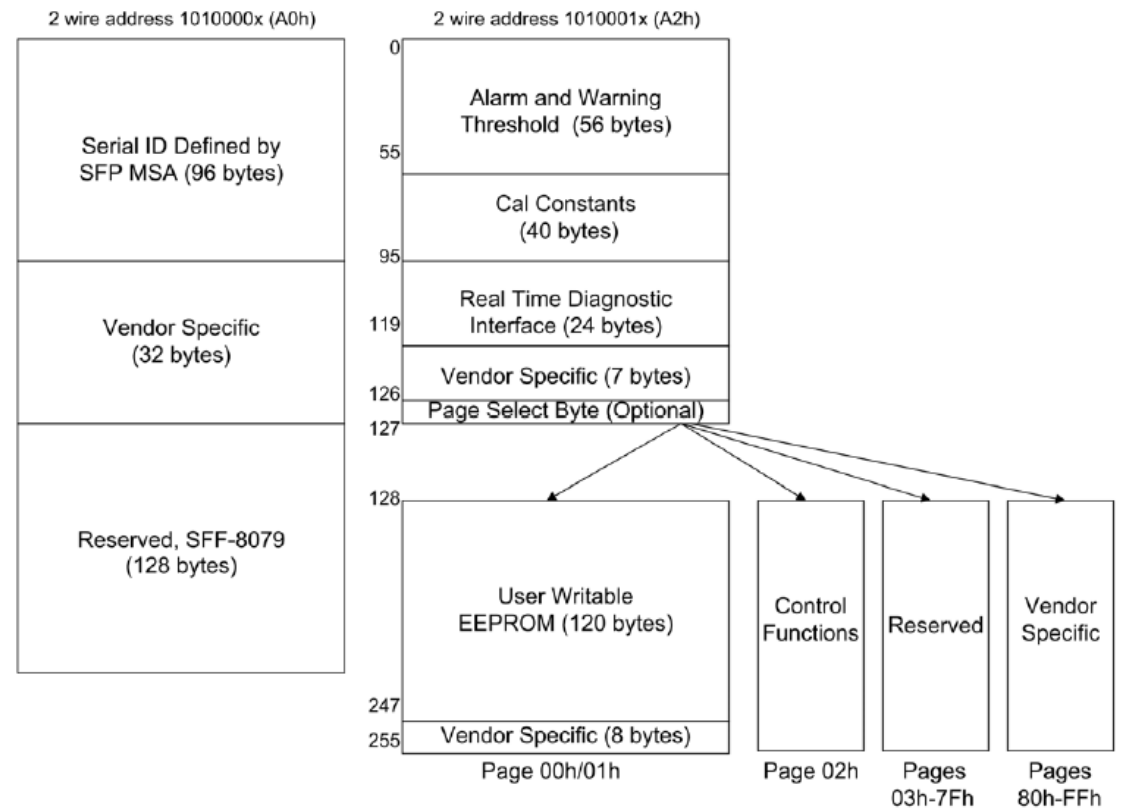

Please select transceiver type from memory database (EEPROM -> Transceivers -> SFP or QSFP or XFP).

7.2.1. SFP and SFP+

- **SFP [A0]** and **SFP [A2]** allows to read/erase/write/verify of A0h and A2h blocks of SFP Transceivers. These blocks may contain also diagnostic or write protected sectors, so verify may not pass for protected sectors.
- **SFP [USER]** allows read/erase/write of any block or page in memory map (verification should be done by user). The [USER] mode allows to read/write specific part of memory.

In block A0h (256bytes) first 128bytes (00h – 7Fh) are for serial ID and vendor information. It may be write protected (password may be required). Second 128bytes (80h-FFh) are reserved.

In block A2h (256bytes) first 127bytes (00h – 7Eh) are diagnostic information (alarm and warning thresholds, cal constants, real time diagnostics) and optional password entry area. 128th byte (7Fh) is page select byte (only if SFP supports pages). Next 128 bytes (80h-FFh) is page content (depends on selected page). SFP may not support A2h block (it will be communication error) or page select (it may contain only single page). Page 00h or 01h is User Writable EEPROM (120bytes) and vendor specific (8bytes). Page 0 may be write protected (password may be required). Page 02h is for control functions. Pages 03h-7Fh are reserved. Pages 80h-FFh are vendor specific.

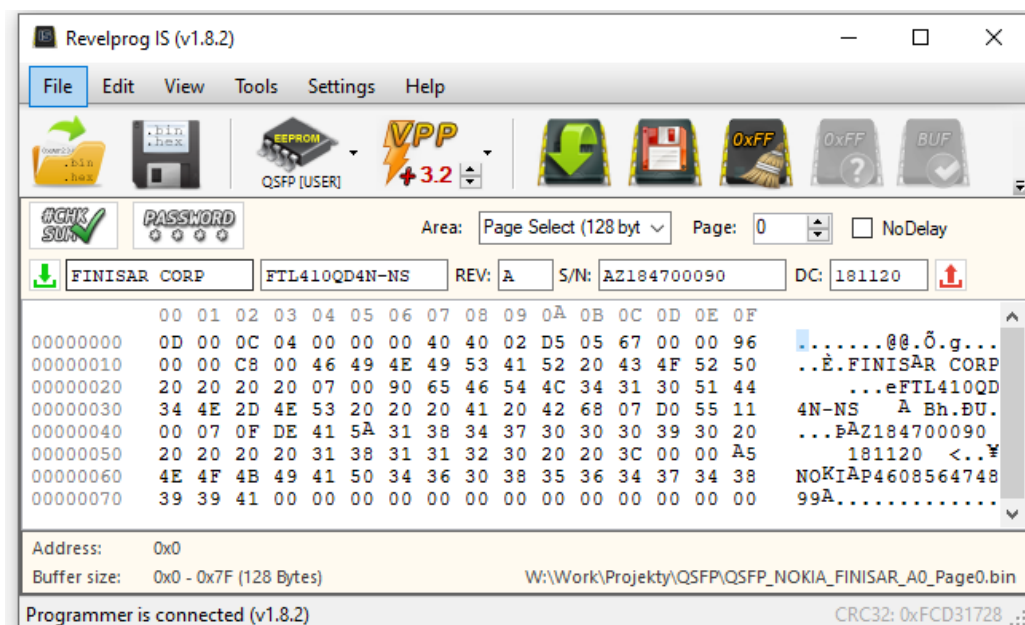

7.2.2. QSFP and QSFP+

- **QSFP [USER]** allows to read/erase/write of any block or page in QSFP/QSFP+ memory map (verification should be done by user). The [USER] mode allows to read/write specific part of memory.

QSFP/QSFP+ contains only block A0h (256 bytes) divided into pages (byte 7Fh in block A0h is page select byte). Pages are 128bytes length. Page 00h is required and provides static module identity and capabilities information (it may be write protected with password). Other pages may be optional.

Please check memory map for your QSFP/QSFP+ or in MSA Standard (SFF-8636 specification).

With REVELPROG-IS you can select page from menu (you do not have to change page bytes manually in buffer) and read/write specific pages:

From	To	Content	No. of bytes	Type
2-Wire Serial Address 1010000x				
Lower Page 00h				
0	2	ID and Status	3	Read-Only
3	21	Interrupt Flags (Clear on read)	19	Read-Only
22	33	Free Side Device Monitors	12	Read-Only
34	81	Channel Monitors	48	Read-Only
82	85	Reserved	4	Read-Only
86	99	Control	14	Read/Write
100	106	Free Side Interrupt Masks	7	Read/Write
107	110	Free Side Device Properties	4	Read-Only
111	112	Assigned to PCI Express	2	Read/Write
113	116	Free Side Device Properties	4	Read-Only
117	118	Reserved	2	Read/Write
119	122	Optional Password Change	4	Write-Only
123	126	Optional Password Entry	4	Write-Only
127	127	Page Select Byte	1	Read/Write
Upper Page 00h				
128	128	Identifier	1	Read-Only
129	191	Base ID Fields	63	Read-Only
192	223	Extended ID	32	Read-Only
224	255	Vendor Specific ID	32	Read-Only
Page 01h (Optional)				
128	255	Reserved (previously for SFF-8079 support)	128	Read-Only
Page 02h (Optional)				
128	255	User EEPROM Data	128	Read/Write
Page 03h (Optional)				
128	175	Free Side Device Thresholds	48	Read-Only
176	223	Channel Thresholds	48	Read-Only
224	229	Tx EQ, Rx Output and TC Support	6	Read-Only
230	241	Channel Controls	12	Read/Write
242	251	Channel Monitor Masks	10	Read/Write
252	255	Reserved	4	Read/Write
Pages 04h-1Fh (Optional)				
128	255	Vendor Specific	128	Read/Write
Pages 20h-21h (Optional)				
128	255	PAM-4 and WDM Features	128	Read/Write
Pages 22h-7Fh (Optional)				
128	255	Reserved	128	Read/Write
Pages 80h-FFh (Optional)				
128	255	Vendor Specific	128	Read/Write

7.2.3. XFP

- **XFP [USER]** allows to read/erase/write of any block or table in QSFP/QSFP+ memory map (verification should be done by user). The [USER] mode allows to read/write specific part of memory.

XFP contains only block A0h (256 bytes) divided into tables (byte 7Fh in block A0h is table select byte). Tables are 128bytes length. Table 01h is default and contains Serial ID Data. Table 02h is User EEPROM. Tables may be write protected (password may be required for erase or write). Other pages may be optional.

Please check memory map for your XFP or in MSA Standard (INF-8077i specification).

With REVELPROG-IS you can select table from menu (you do not have to change page bytes manually in buffer) and read/write specific tables.

7.3. Protected transceivers: manufacturer password and host password

Some transceivers also provides an optional password entry location that may be used to protect vendor internal function or user writable memory. Password shall not be required to read any data, but it may be used for write protection for specific areas. Nor shall passwords be required to write any controls defined in the digital diagnostics functions. Passwords may be used by vendors to control write access to MSA defined read only data for factory setup, or to OEMs to limit write access in the User EEPROM area. Finally, passwords may be used to control read or write access to the vendor specific pages or tables. Separate passwords value ranges will be defined to prevent accidental writing to critical module control areas. There are 2 types of passwords: manufacturer password and host password (also known as user password). You can enter password using password tool in REVEPLROG-IS application.

7.3.1. Host/User password

Host password is protecting User Writable EEPROM. Entering valid user password will unlock only user eeprom for erase and write operations. Location of this area depends on transceiver type (please check memory map for your transceiver). In most cases user can change this password (if current password is known). All factory new transceivers should have default host password: 00h 00h 10h 11h.

7.3.2. Manufacturer password

Manufacturer password is protecting whole memory map, e.g. serial number, product name, manufacturer name, vendor specific areas etc. Entering valid manufacturer password will unlock all memory map for erase and write operations. Only manufacturer know this password, but REVELPROG-IS provides tool for searching password with brute force method.

7.3.3. Hacking password (brute-force method)

REVELPROG-IS password tool for transceivers can be also used to search password using brute force method (checking all combinations or limited range of combinations). It uses smart algorithm with auto-adjusting communication speed and delays to check as many password as possible in shortest time. For fastest MCU based transceivers it's possible to check 4000 password combinations per second. Please check more details and on REVELTRONICS forum:

<https://forum.reveltronics.com/viewtopic.php?f=31&t=527>

8. Updates

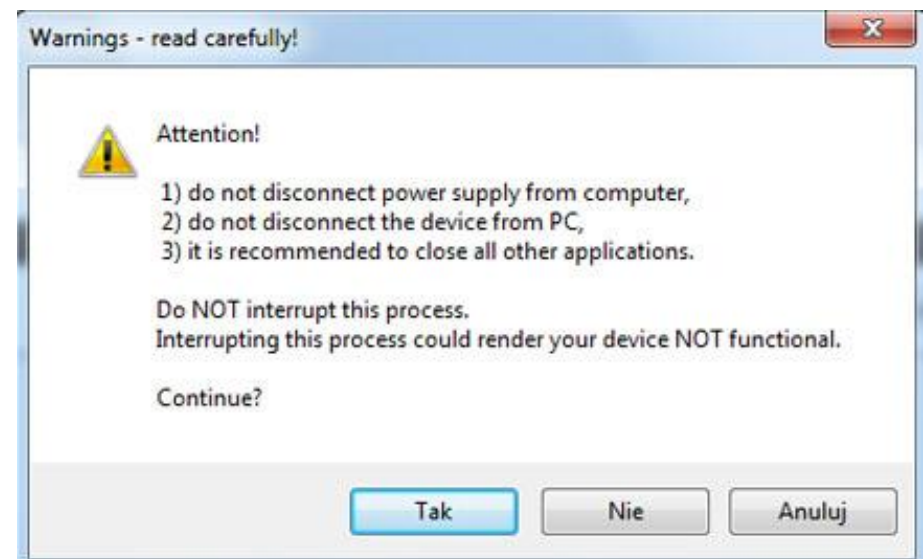

New trends on the market and latest devices require from users newer and newer programming devices. Customer's satisfaction is our number one priority and we share updates free of charge for all users of REVELPROG-IS. Update consist of software update (pc application) and firmware update (software inside the device). Latest software can be downloaded directly from manufacturer's webpage. You will be informed by the software about possible updates after connecting out of date device.

Caution! If a firmware update process is interrupted, your programmer may not function properly. Updates are optional – warranty does not cover damage due improper care.

During update process, device will start in DFU (Device Firmware Upgrade) mode. First time it may be necessary to install additional drivers (for DFU mode). Windows should find drivers automatically on the Internet (if not, there are also available in `/drivers/DFU` subdirectory in the installation folder). Installing drivers process should take about 30 seconds. If DFU drivers are installed, application will update the firmware device. Appropriate instructions will be displayed before.

Please close all other applications and disable antivirus software during update process. Do not disconnect and do not connect any USB devices during update process. Make sure that you have stable power supply for PC.

Update process may take about half a minute. Progress will be displayed on the screen. There is no possibility to cancel this process! After successful update, device will restart and will be ready to use.

9. Research and development

We are keen to still develop and improve the device. Please contact us at lab@reveltronics.com or visit our contact page at www.reveltronics.com if you have any comments or tips about REVELPROG-IS.

Very welcome are ideas:

- how to improve REVELPROG-IS - what functionality add to it,
- what chips add to supported device list in the next update (please suggest only serial I2C, SPI, uWire devices).

Repeated suggestions from many users will have more chance for implementation in the future. We encourage you to contact us because in this way we already added many devices popular only in small segments of automotive market, computer service, RTV/AGD devices etc.

10. APPENDIX A - List of supported devices

The following list details the family of supported devices (left column) with selected examples of supported memories (right column). Most chips have the same programming procedures – programmer supports more devices than the examples given in the list.

EEPROM I2C 24... series

24..01 (1kb)	24AA01 24AA014 24AA014H 24AA01H 24C01 24C01A 24C01B 24C01C 24LC01 24LC014 24LC014H 24LC01B 24LC01BH AF24BC01 AT24C01 AT24C01A AT24C01B BR24A01AF BR24A01AFJ BR24C01 BR24C01A BR24C01AF BR24C01AFJ BR24C01AFV BR24C21F BR24C21FJ BR24C21FV BR24G01 BR24G01F BR24G01FJ BR24G01FV BR24G01FVT BR24L01 BR24L01A BR24L01AF BR24L01AFJ BR24L01AFV BR24L01AFVM BR24L01AFVT BR24T01A CAT24AA01 CAT24C01 CAT24C01B CAT24C21 CAT24FC01 CAT24LC01 CAT24WC01 CR24C01 CY24C01 FM24C01 FT24C01 FT24C01A GE24C01 GP24BC01 HM24LC01 HT24C01 HT24LC01 IS24C01 IS24C01B LT24C01 LX24C01 M24C01 MM24C01 S-24C01A S-24C01B S-24C01C S-24CS01A SLA24C01 SLE24C01 ST24C01 ST24W01 TMC24A01 TU24C01B UG24C01 X24012 X24C01 X24C01A XL24C01A

EEPROM SPI 90... series

(1kb - 4kb)	BR9010 BR9020 BR9040
-------------	--------------------------

EEPROM 1-Wire devices

Supports 1-wire devices and battery chips

DS... MAX...	DS2430A DS2431 MAX31826 DS2433 DS24B33 DS28EC20 DS2434 DS2436
-----------------	---

FLASH SPI 25... series

Supports low-voltage serial flash memories (1.2V, 1.8V, 2.5V) and standard (3.3V)

SFP / SFP+ / QSFP / QSFP+ / XFP optical & ethernet modules

Please note!

- there is SFP/QSFP/XFP adapter required with external power supply,
- MSA standard is supported (e.g. SFF-8472, SFF-8636, INF-8077i),
- possibility to enter manufacturer/host password and program write protected transceivers,
- brute force password tool (searching password for protected transceivers with unknown password),
- change manufacturer info, model, serial number etc. and recalculate checksums directly from REVELPROG-IS application

SFP / SFP+ (MSA standard: 0xA0, 0xA2, page 0-255)	SFP and SFP+, read/write block 0xA0 (256B), read block 0xA2 (256B), read/write page 0-255 (128B), standard MSA example manufacturers: GBC, HUAWEI, GPON, JDSU, MIKROTIK, OPTEC, OPTION, WTD and other OEM
QSFP / QSFP+ (MSA standard: 0xA0, page 0-255)	QSFP and QSFP+, read/write A0h block (256B), read/write 0-255 page (128B), standard MSA example manufacturers: CISCO, HP, FINISAR, NOKIA, HUAWEI, JDSU and other OEM
XFP (MSA standard: 0xA0, table 0-255)	XFP, read/write A0h block (256B), read/write 0-255 table (128B), standard MSA example manufacturers: 10GTEK, CISCO, FINISAR, OPNEXT, JDSU and other OEM

Your suggestions

If you have any suggestion for supported device list please contact us at lab@reveltronics.com. There is possibility to add any serial device with I2C, SPI or uWire interface (EEPROM/FLASH/FRAM).
